Chapter III

Trust Models for Ubiquitous Mobile Systems

Mike Burmester, Florida State University, USA

ABSTRACT
This chapter introduces the notion of trust as a means to establish security in ubiquitous mobile network systems. It argues that trust is an essential requirement to enable security in any open network environments, and in particular, in wireless ad hoc environments where there is no network topology. In such environments, communication can only be achieved via routes that have to be trusted. In general it may be hard, or even impossible, to establish, recall, and maintain trust relationships. It is therefore important to understand the limitations of such environments and to find mechanisms that may support trust either explicitly or implicitly. We consider several models that can be used to enable trust in such environments, based on economic, insurance, information flow, and evolutionary paradigms.
INTRODUCTION

Wireless mobile networks are a paradigm for mobile communication in which wireless nodes do not rely on any underlying static network infrastructure for services such as packet routing, name resolution, node authentication, or distribution of computational resources. The communication medium is broadcast. Nodes in range communicate in a direct peer-to-peer manner, while nodes out of range establish routing paths dynamically through other nodes where possible. The recent rise in popularity of mobile wireless devices and technological developments have made possible the deployment of wireless mobile networks for several applications. Examples include emergency deployments, disaster recovery, search-and-rescue missions, sensor networks, military (battlefield) operations, and more recently e-commerce. Since the network nodes are mobile, the network topology frequently changes: Communication links are established or broken as nodes move in and out of range, and the network may get partitioned with the connectivity restricted to the partitions. As a result it may be much harder (or even impossible) to establish trust associations.

The trend in trust management is to view trust implicitly through delegation of privilege via certificates. Certificates can be chain-linked (linking à priori trust relationships) and used to propagate and distribute trust over insecure media, without the danger of being manipulated.

In this chapter, we give an overview of several models that can be used to support trust in mobile networks, based on economic, insurance, information flow, and evolutionary paradigms.

TRUST IN WIRELESS MOBILE NETWORKS

We consider environments in which there may be no fixed underlying network infrastructure, such as static base stations, for services such as packet routing, name resolution, node authentication, or the distribution of computational resources. In such environments, recalling and maintaining trust relationships is particularly challenging. Mobile systems share many of the complexities of fixed infrastructure systems. For example, nodes may have (Burmester & Yasinsac, 2004):

1. No prior relationship or common peers
2. No shared proprietary software
3. Different transmission, memory and processing capabilities
4. Different mobility characteristics
5. Different lifetime properties
