Chapter 8
Composing and Coordinating Transactional Web Services

ABSTRACT
Composite applications leveraging the functionalities offered by Web services are today the underpinnings of enterprise computing. However, current Web services composition systems make only use of functional requirements in the selection process of component Web services while transactional consistency is a crucial parameter of most business applications. The transactional challenges raised by the composition of Web services are twofold: integrating relaxed atomicity constraints at both design and composition time and coping with the dynamicity introduced by the service oriented computing paradigm. This chapter proposes a new process to automate the design of transactional composite Web services. This solution for Web services composition does not take into account functional requirements only but also transactional ones based on the Acceptable Termination States model. The resulting composite Web service is compliant with the consistency requirements expressed by business application designers and its execution can easily be coordinated using the coordination rules provided as an outcome of the authors’ approach. An implementation of these theoretical results augmenting an OWL-S matchmaker is further detailed as a proof of concept.

INTRODUCTION
Web services composition has been gaining momentum over the last years as a means of leveraging the capabilities of simple operations to offer value-added services. Complex services such as airline booking systems can be designed as the aggregation of Web services offered by different organizations. As for all cross-organizational collaborative systems, the execution of composite services requires transactional properties so that the overall consistency of data modified during
the process is ensured. Yet, existing Web services composition systems appear to be limited when it comes to integrating at the composition phase, the consistency requirements defined by designers in addition to functional matchmaking. Composite Web services indeed require different transactional approaches than the ones developed for usual database systems (Elmagarmid, 1992), (Greenfield, Fekete et al. 2003). The transactional challenges raised by the composition of Web services are twofold. First, like classical workflow systems, composite services raise less stringent requirements for atomicity in that intermediate results produced by some components may be kept without rollback despite the failure to complete the overall execution of a composite service. Second, composite services are dynamic in that their components can be automatically selected at run-time based on specific requests. Existing approaches only offer means to validate transactional requirements once a composite Web service has been created (Bhiri, Perrin et al. 2005) and do not address the integration of these requirements into the composite application building process.

In this chapter, we propose a systematic procedure to automate the design of transactional composite Web services. Given an abstract representation of a process wherein instances of services are not yet assigned to component functional tasks, our solution enables the selection of Web services not only according to functional needs but also based on transactional requirements. In this approach, transactional requirements are specified by designers using the Acceptable Termination States (ATS) model. The resulting composite Web service is compliant with the defined consistency requirements and its execution can be easily coordinated as our algorithm also provides coordination rules that can be integrated into a transactional coordination protocol. Besides, the theoretical results developed in our approach have been implemented as a proof of concept and integrated into an OWL-S (OWL Services Coalition, 2003) functional matchmaker providing it with transactional matchmaking capabilities.

The remainder of the chapter is organized as follows. Section 2 and 3 introduce the methodology of our approach and a motivating example, respectively. In section 4, the transactional model underpinning this work is outlined. In section 5 we provide details on the termination states of a composite Web service then in section 6 we describe how transactional requirements are formed based on the properties of the termination states. The transaction-aware composition process through which transactional composite Web services are designed is detailed in section 7 while the implementation of our results in an OWL-S based framework is presented in section 8. Finally, section 9 discusses related work and section 10 presents the conclusion.

PRELIMINARY DEFINITIONS AND METHODOLOGY

Consistency is a crucial aspect of composite services execution. In order to meet consistency requirements at early stages of the service composition process, we need to consider transactional requirements a concrete parameter determining the choice of the component Web services. In this section we present a high level definition of the consistency requirements and a methodology taking into account these requirements during the composition of Web services.

Consistent Composite Web Services

A composite Web service \( W_s \) consists of a set of \( n \) Web services \( W_s = \{ s_a \}_{a \in [1,n]} \) whose execution is managed according to a workflow \( W \) which defines the execution order of a set of \( n \) tasks \( W = \{ t_a \}_{a \in [1,n]} \) performed by these services (for the sake of simplicity, we consider in our approach that a given service executes only one task). The assignment of services to tasks is performed by means of composition engines based on functional requirements. Yet, the execution of a composite
