INTRODUCTION

Information systems were developed in early 1960s to process orders, billings, inventory controls, payrolls, and accounts payables. Soon information systems research began. Harry Stern started the “Information Systems in Management Science” column in Management Science journal to provide a forum for discussion beyond just research papers (Banker & Kauffman, 2004). Ackoff (1967) led the earliest research on management information systems for decision-making purposes and published it in Management Science. Gorry and Scott Morton (1971) first used the term decision support systems (DSS) in a paper and constructed a framework for improving management information systems. The topics on information systems and DSS research diversifies. One of the major topics has been on how to get systems design right.

As an active component of DSS, data warehousing became one of the most important developments in the information systems field during the mid-to-late 1990s. It has been estimated that about 95% of the Fortune 1000 companies either have a data warehouse in place or are planning to develop one (Wixon & Watson, 2001). Data warehousing is a product of business need and technological advances. Since business environment has become more global, competitive, complex, and volatile customer relationship management (CRM) and e-commerce initiatives are creating requirements for large, integrated data repositories and advanced analytical capabilities.
By using a data warehouse, companies can make decisions about customer-specific strategies such as customer profiling, customer segmentation, and cross-selling analysis (Cunningham, Song, & Chen, 2006). To analyze these large quantities of data, data mining has been widely used to find hidden patterns in the data and even discover knowledge from the collected data. Thus how to design and develop a data warehouse and how to use data mining in the data warehouse development have become important issues for information systems designers and developers.

This article presents some of the currently discussed development and design methodologies in data warehousing and data mining, such as the multidimensional model vs. relational entity-relationship (ER) model, corporate information factory (CIF) vs. multidimensional methodologies, data-driven vs. metric-driven approaches, top-down vs. bottom-up design approaches, data partitioning and parallel processing, materialized view, data mining, and knowledge discovery in database (KDD).

BACKGROUND

Data warehouse design is a lengthy, time-consuming, and costly process. Any wrongly calculated step can lead to a failure. Therefore, researchers have placed important efforts to the study of design and development related issues and methodologies.

Data modeling for a data warehouse is different from operational database, for example, online transaction processing (OLTP), data modeling. An operational system is a system that is used to run a business in real time, based on current data. An OLTP system usually adopts ER modeling and application-oriented database design (Han & Kamber, 2006). An information system, like a data warehouse, is designed to support decision making based on historical point-in-time and prediction data for complex queries or data min-
