INTRODUCTION

Information systems were developed in early 1960s to process orders, billings, inventory controls, payrolls, and accounts payables. Soon information systems research began. Harry Stern started the “Information Systems in Management Science” column in Management Science journal to provide a forum for discussion beyond just research papers (Banker & Kauffman, 2004). Ackoff (1967) led the earliest research on management information systems for decision-making purposes and published it in Management Science. Gorry and Scott Morton (1971) first used the term decision support systems (DSS) in a paper and constructed a framework for improving management information systems. The topics on information systems and DSS research diversifies. One of the major topics has been on how to get systems design right.

As an active component of DSS, data warehousing became one of the most important developments in the information systems field during the mid-to-late 1990s. It has been estimated that about 95% of the Fortune 1000 companies either have a data warehouse in place or are planning to develop one (Wixon & Watson, 2001). Data warehousing is a product of business need and technological advances. Since business environment has become more global, competitive, complex, and volatile customer relationship management (CRM) and e-commerce initiatives are creating requirements for large, integrated data repositories and advanced analytical capabilities.

By using a data warehouse, companies can make decisions about customer-specific strategies such as customer profiling, customer segmentation, and cross-selling analysis (Cunningham, Song, & Chen, 2006). To analyze these large quantities of data, data mining has been widely used to find hidden patterns in the data and even discover knowledge from the collected data. Thus how to design and develop a data warehouse and how to use data mining in the data warehouse development have become important issues for information systems designers and developers.

This article presents some of the currently discussed development and design methodologies in data warehousing and data mining, such as the multidimensional model vs. relational entity-relationship (ER) model, corporate information factory (CIF) vs. multidimensional methodologies, data-driven vs. metric-driven approaches, top-down vs. bottom-up design approaches, data partitioning and parallel processing, materialized view, data mining, and knowledge discovery in database (KDD).

**BACKGROUND**

Data warehouse design is a lengthy, time-consuming, and costly process. Any wrongly calculated step can lead to a failure. Therefore, researchers have placed important efforts to the study of design and development related issues and methodologies.

Data modeling for a data warehouse is different from operational database, for example, online transaction processing (OLTP), data modeling. An operational system is a system that is used to run a business in real time, based on current data. An OLTP system usually adopts ER modeling and application-oriented database design (Han & Kamber, 2006). An information system, like a data warehouse, is designed to support decision making based on historical point-in-time and prediction data for complex queries or data mining applications (Hoffer, Prescott, & McFadden, 2007). A data warehouse schema is viewed as a dimensional model (Ahmad, Azhar, & Lukauskis, 2004; Han & Kamber, 2006; Levene & Loizou, 2003). It typically adopts either a star or snowflake schema and a subject-oriented database design (Han & Kamber, 2006). The schema design is the most critical to the design of a data warehouse.

Many approaches and methodologies have been proposed in the design and development of data warehouses. Two major data warehouse design methodologies have been paid more attention. Inmon, Terdeman, and Imhoff (2000) proposed the CIF architecture. This architecture, in the design of the atomic-level data marts, uses denormalized entity-relationship diagram (ERD) schema. Kimball (1996, 1997) proposed multidimensional (MD) architecture. This architecture uses star schema at atomic-level data marts. Which architecture should an enterprise follow? Is one better than the other? Currently, the most popular data model for data warehouse design is the dimensional model (Bellatreche & Mohania, 2006; Han & Kamber, 2006). Some researchers call this model the data-driven design model. Artz (2006) advocates the metric-driven view, which, as another view of data warehouse design, begins by identifying key business processes that need to be measured and tracked over time in order for the organization to function more efficiently. There has always been the issue of top-down vs. bottom-up approaches in the design of information systems. The same is with a data warehouse design. These have been puzzling questions for business intelligent architects and data warehouse designers and developers. The next section will extend the discussion on issues related to data warehouse and mining design and development methodologies.
