Chapter 4.13
Web Services Security in E-Business:
Attacks and Countermeasures

ABSTRACT

Web services enable the communication of application-to-application in a heterogeneous network and computing environment. The powerful functionality of Web services has given benefits to enterprise companies, such as rapid integrating between heterogeneous e-business systems, easy implementation of e-business systems, and reusability of e-business services. While providing the flexibility for e-business, Web services tend to be vulnerable to a number of attacks. Core components of Web services such as simple object access protocol (SOAP), Web services description language (WSDL), and universal description, discovery, and integration (UDDI) can be exploited by malicious attacks due to lack of proper security protections. These attacks will increase the risk of e-business that employs Web services. This chapter aims to provide a state-of-the-art view of Web services attacks and countermeasures. We examine various vulnerabilities in Web services and then followed by the analysis of respective attacking methods. We also discuss preventive countermeasures against such attacks to protect Web services deployments in e-business. Finally, we address future trends in this research area.

INTRODUCTION

As the use of the Internet and the World Wide Web (WWW) is expanding rapidly, more and more companies are implementing e-business using Web technologies to replace the traditional business model. Conventional Web application is
human-centric, which relies on lots of time-consuming human intervention. The development of Web services technology has changed this computing paradigm to application-centric.

A Web service is any piece of software that supports interoperable program-to-program interaction over a network (Booth, Haas, McCabe, Newcomer, Champion, Ferris, et al., 2004). This technology is not tied to any specific operating systems and programming languages. Thus, it enables the communication of application-to-application in a heterogeneous network and computing environment. This allows enterprise companies to implement and integrate their e-business systems rapidly. Also, reusability of e-business services becomes easy. All of these benefits are a great attraction for enterprise companies to adopt Web services in their e-business environment.

While Web services provide the flexibility for e-business, they introduce security issues that are less known in the e-business communities. The objective of this chapter is to address security challenges presented in Web services and explain which types of solutions are plausible for countering Web services attacks. In the following sections, we review current Web services technology, present different attacks against Web services, discuss some of the security countermeasures, suggest directions for future research, and present a conclusion of this chapter.

**WEB SERVICES ARCHITECTURE**

A Web services architecture (Booth et al., 2004) is a set of systems and protocols that facilitate application-to-application communication over a network. There are many technologies that are related to the Web services architecture. The main building blocks (Figure 1) that we describe here are extensible markup language (XML) (Bray, Paoli, Sperberg-McQueen, Maler, & Yergeau, 2004), simple object access protocol (SOAP) (Gudgin, Hadley, Mendelsohn, Moreau, & Nielsen, 2003a, 2003b; Mitra, 2003), Web services description language (WSDL) (Booth, & Liu, 2005; Chinnici, Haas, Lewis, Moreau, Orchard, & Weerawarana, 2005; Chinnici, Moreau, Ryman, & Weerawarana, 2005), and universal description, discovery, and integration (UDDI) (Clement, Hately, Riegen, & Rogers, 2004).
