ABSTRACT

E-health is a rising star that marks the collaboration of medical science and information technology, a ray of hope promising a glorious future of health and prosperity, an easy solution to rely on when in need of medical assistance. But the question arises is E-health an absolute spotless option? In this paper we question the integrity with which e-health is being practised, is the code of ethics being diligently followed? And if not then is ethical e-health entirely impossible? It is of utmost importance to encourage the motivational thinkers who have taken the initiative to provide a better and quicker solution to all health problems by integrating health services and information technology. To do so it becomes necessary to remove the barriers in the way of ethical E-health.

Keywords: Accountability, Code of Ethics, E-Health, Internet, Quality of Information

INTRODUCTION

In recent time, technological developments have made dramatic impact on our lives. In early 90s, Telematics which is blending of computers and wireless telecommunication system, with the goal for efficiently transmitting the information to vast health care network. It played a major role in medical informatics and health care. E-health or health information technology is the latest buzzword in the arena of “computerized medicine”, which barely came into practice before 1999. Sole motto of e-health is to provide better, faster and more convenient health care services through digital technology. In e-health storing, managing and accessing the patient’s medical records is done using the computer networks instead of conventional paper records. E-health activities comprise e-consult, tele-medicine, sharing of electronic health records, etc. All this improve the patient’s access with the physician or clinician thus improving the health care system.

The motion of e-health is becoming customary in the today’s society. And it has the potential to revolutionize the health care delivery system across the world. It paves the way for better and more convenient health care
system. It supports the people in the far off places or living in remote areas to extend the access to specialist health care services. Information about the patient’s health is electronically made available to the health care providers which will help in getting better treatment and care. It allows the patients to have access to the electronic health records of their own and in some cases, provide input to their own record, but this was one side of the coin and the other side is, sharing of patient’s information over the unsecure open network may lead to tampering or corruption of the patient’s information so it is subjected to appropriate security to ensure the recipient about the credibility of the information retrieved.

The advancement of technology viz. email, online banking, internet, online shopping, etc has lead to the rising expectations for improved health technologies for better survival of the population, at the same time cost effectiveness and quality of the health care must be retained. Despite advancement of information technology, the health care industry has been lagging in the adopting and optimizing the use of technology for better health care services. All this has lead to the increased pressure in the prevailing health care resources. To overcome these challenges each country is pursuing its own solutions. But there is a sole need of much generalized solution for these challenges which can be conquered by e-health.

E-health leads to the improvement of the health care facility not only locally or regionally but globally. With millions portraying interest and showing enthusiasm in the genre of e-health, it becomes obligatory to understand the concept of e-health in its entirety, the impact caused the pros and cons and thus it becomes a prerequisite to visualize the road that we walk on, led by a notion quite vague in understanding, yet adopted by many practically. E-health, its definition is broader than just internet and medicine. Some of the vital area e-health circumscribes are:

- E-consults or e-visits between patients and the physician or health care provider.
- Patient’s can seek for health opinion from their physician or clinical team.
- Patient’s interaction with their own electronic health records.

All this improves patient’s access to physician or clinicians and the health care services.

The proliferation of ehealth has lead to an all new model of patient-physician interaction which has proved to be not only more convenient but also cost effective health care in order to replace the conventional face to face interaction. Primarily the goals for implementing ehealth are:

- To improve and increase the access to the health care facilities for the individuals who live rural or remote areas.
- Personalized treatment.
- To broaden the capacity of physician or health care provider.
- Improved patient-physician interaction.
- Increased patient’s access to their health records and patient’s participation or self management of his or her health.
- Cost efficient health care.

And as they have rightly said “Every good comes with a bad” and “Partial knowledge is the masterpiece recipe of failure”, it further necessitates the urgency to look into the drawbacks involved in the concept called E-health. But the question arises, what is E-health. It is the collaboration of medicinal services and information using information technology via the Internet [1, 2]. E-health services are being used extensively by doctors to communicate and extend their reach to other countries and continents. Medical cases are being discussed and solved via video conferences. The common man is searching the World Wide Web for medical assistance, and also to completely understand a doctor’s diagnosis. With the population of the world increasing hand in hand it becomes challenging to maintain records of patients, their diseases and personally attend to each. Doctors are being relieved of some of the work pressure
