Chapter 12
Development and Progress of the Mining Association of Canada’s Towards Sustainable Mining Program

Michelle Edith Jarvie-Eggart

ABSTRACT

Early efforts to address sustainability within the mining industry (GMI and ICMM) did not create a common set of protocols by which individual operations could be clearly ranked on their performance. Although the Global Reporting Initiative (GRI) does provide protocols for the reporting of sustainability indicators for mining operations, GRI-based reports include a letter grade based on report completeness, not performance on the actual indicators. The Mining Association of Canada’s Towards Sustainable Mining (TSM) program provides protocols to address biodiversity, tailings management, crisis management, safety and health, energy/GHGs, and Aboriginal/community engagement. The TSM-based reports grade mining operation performance at implementing programs and systems to address each of these topics. Progress along these indicators tells us how well the industry is doing at addressing sustainability along each concept, and where further progress is still needed.

INTRODUCTION

Increasingly the mining industry is faced with demands to address their triple bottom line throughout the lifecycle of a mining operation. Public outcry against poor environmental and social performance in the industry can stymie the permitting process, preventing new mines from developing. Both the industry and public can benefit from an honest and realistic assessment of the social, environmental, and economic impacts of mining, and attempts to reduce and mitigate the most significant impacts. In response to public concerns surrounding the impacts of the mining industry, the Mining Association of Canada (MAC) developed a program called Towards Sustainable Mining (TSM), including sustainability indicators on which member companies of MAC are required...
to report. This chapter provides a summary of the program, reporting results across the mining industry within Canada, the progress made by the industry since the inception of the program, and opportunities for further improvement.

BACKGROUND

With increasing global population comes ever more competition for the Earth’s finite mineral resources. Unfortunately, minerals are not distributed evenly on the planet, leaving some countries comparatively richer in minerals than others. Canada is among the leading mining countries in the world. With over 3,000 companies mining in Canada, its main products include potash, sulfur, uranium, aluminum, cobalt, gem-quality diamonds, refined indium, nickel, platinum-group metals, sodium sulfate, and zinc (USGS 2011). As the world’s second largest country by area, Canada has vast amounts of wilderness and roadless areas (CIA, 2009). Through Canada’s Aboriginal populations of the First Nations, Inuit, and Métis, Canada also has a unique cultural heritage and connection to its natural environment. Canada’s diverse society, expansive wilderness environment, and vast mineral resources have all contributed to the need for efforts to balance the social, environmental, and economic impacts of the mining industry. To better understand how these impacts can be addressed through sustainability programs, we must first revisit what it is that sustainability means.

 Definitions of Sustainability

In 1983, to answer the global community’s questions on how to best guide development, the United Nations convened the World Commission on Environment and Development (WCED). As the Commission was chaired by Gro Harlem Brundtland, the Prime Minister of Norway, it came to be known as the Brundtland Commission. The Brundtland Commission was created to address the growing concern “about the accelerating deterioration of the human environment and natural resources and the consequences of that deterioration for economic and social development.” The Brundtland Commission’s 1987 report, Our Common Future, defined sustainable development as “development that meets the needs of the present without compromising the ability of future generations to meet their own needs.” This definition is considered the original, and is probably the most quoted, definition of sustainable development. It also begs the questions of whether extractive industries can ever be truly sustainable.

The act of mining a finite resource results in an ever dwindling amount available for future generations to consume. Some mined materials can be reused. Recycling of metals can help to maintain the amount of total metal available for the use of future generations. But mined fuels are consumed in their use, such as coal and bituminous oil sands, leaving less available for future needs. It is obvious that the extraction of finite resources cannot continue indefinitely. At some theoretical point in time, all available mineral resources could be mined. How then, can the term sustainability be applied to the mining industry? The answer lies in the evolution of the concept of sustainability, as it is applied to the business world.

John Elkington is often credited with the integration of sustainability concerns into the business world. Traditionally, business has only concerned itself with the economic bottom line as a measure of success. In his 1998 book, Cannibals with Forks: the Triple Bottom Line of 21st Century Business, John Elkington coined the phrase “Triple Bottom Line” (TBL) as a new means of accounting. Elkington advised for an expansion of the traditional accounting framework to consider environmental and social performance in addition to the traditional business metric of financial performance. The triple bottom line includes the three elements (or pillars) of sustainability as environment, economy, and society, which must all
