Google Earth Revisited: 
Case Studies at the Plain of Larissa (Thessaly, Greece)

Dimitris Kaimaris, Aristotle University of Thessaloniki, Thessaloniki, Greece
Petros Patias, Aristotle University of Thessaloniki, Thessaloniki, Greece
Olga Georgoula, Aristotle University of Thessaloniki, Thessaloniki, Greece

ABSTRACT

The interpretation of photos and the processing of Google Earth imagery which allowed the “random” discovery, as a result of a non-systematical research, of a numerous marks of buried constructions in the wide area of the city of Larisa (Thessaly, Greece) is presented in this project. Additional data as aerial photographs over time, satellite images and the digital terrain model of the same area has been used. From the numerous marks, this project mainly focuses on three positions where the positive marks (soilmarks or/and cropmarks), circular or/and linear, reveal on a satisfying level covered construction of great dimensions. The ongoing research activity of the editorial team along with this research highlights the advantages of using Google Earth imagery in an attempt to “random” mark of unknown covered constructions, or, in the frame of a systematic survey of aerial and remote sensing archaeology, as additional and not exclusive source of information.

KEYWORDS

Aerial Archaeology, Buried Constructions, Google Earth, Marks, Remote Sensing Archaeology

INTRODUCTION

Google Earth (GE) can be characterized as a complementary and thus helping tool in the frame of a systematic survey of aerial and remote sensing archaeology (Kaimaris et al., 2011). More specifically, apart from the main use of GE imagery in archaeology, which is the observation and further study of known archaeological positions, in some occasions the imagery itself has led to a “random” tracing of unknown covered constructions. On the other hand, there have been times when the GE imagery would not provide the researcher with enough information in areas where other tools of archaeology prospections (Figure 1), such as for example historic maps and aerial photographs, allowed the detection of interesting locations for further study (Kaimaris et al. 2011, Palmer 2005, Thomas et al. 2008, Myers and Camp 2010, Myers 2010, Cowley and Palmer 2009, Jia and Nie 2009, Micle et al. 2009, Jacobs 2013, Handwerk 2006). This paper focuses on the “random” tracking of possible unknown large covered constructions via the use of GE. Subsequently, aerial photographs over time were gathered and studied confirming our initial suspicions. Afterwards, the supply of a satellite image of specific date (Kaimaris, 2012) followed and terrain of the study area was analyzed.

The collection of aerial photographs and satellite images over time are of major importance, and is one of the key components of the methodology of aerial and remote sensing archaeology, as far as covered structures tracking surveys are concerned. The continuous appearance of a mark over time confirms its presence and increases the likelihood of a covered construction. Otherwise, ie
the presence of a mark in a single aerial photograph or satellite image, while it is absent in images over time, can lead to the conclusion that the mark might occur due to a covered construction and appeared due to special weather conditions (Featherstone et al., 1999), but it may also not be caused by a covered structure but by surface factors, such as, e.g. the geometry of the seed or the path of harvesting machines, etc.

STUDY AREA

The city of Larissa (Figure 2) is constructed on the riverside of Pineios River and is located in the center of the eastern part of Thessaly’s plain, which is covered almost in full by the regional unit of Larissa. Meanwhile, its altitude from the sea level is 72m.

The regional unit’s allocation of land is by 45,3% plain, 24,4% semi-mountainous and 30,3% mountainous. At the regional unit’s north the following mountains are found: Karbounis, Titarow and Mount Olympus. At the regional unit’s eastern part Mounts Kissavos and Maurovouni are found, sierra Anthiasia is located at the northwest and a part of the sierra Othiros of the Narthakio mountain is located at the south of the municipality. The largest part of the plain area is shaped in the middle of the regional unit of Larissa and forms the plain of Larissa-Tyrnavos, one of the largest plain of the whole country. Its extent reaches 589 m2 and it covers its needs for water by Pineios River. The south part of the regional unity is covered by the plain of Farsala.

The Antiquities of Larissa is one of the Regional Offices of the Ministry of Culture and Sport. It is based in Larissa and its responsibility spans to the whole extent of the Regional Unit of Larissa. The period covered by the office’s activities ranges from the prehistoric to the post-Byzantine period and the period of Ottoman rule. Its responsibilities included: detections of monuments, recording of memorials and any moving object, excavations, restoration works, monuments enhancement works and premises, maintenance of movable and immovable monuments, establishment of new museums and collections, organization of temporary exhibitions, organization of educational programs, cultural events and, lastly, organization of conferences.

Larissa is the capital of Thessaly and has been inhabited for almost 4,000 years. Archeological research proves that the city and its wider region is inhabited from the Paleolithic Era. During the ancient times, the city had its own coin. Hippocrates, the father of Medicine, lived and died in Larissa.
