Chapter VI

Conceptual Modeling of Virtual Environments Using Hypermedia Design Techniques

Abstract

Traditionally, the development of virtual environments has been tightly dependent on the programmer’s skills to manage the available toolkits and authoring systems. In such a scenario, the discussion of different design alternatives, future changes and maintenance, interoperability, and software reuse are all of them costly and quite difficult. In order to overcome this...
unsystematic and technology-driven process, conceptual modeling has to be included just before the implementation phase to provide a shared representation language that facilitates the communication among the different team members, including stakeholders, as well as the reuse and redesign for future requirements since conceptual models hide implementation details and constraints, and are cheaper and easier to produce than prototypes. As a first attempt to attain these aims, this chapter presents the basis of a constructional approach for the VE conceptual modeling through a set of complementary design views related to the VE components and functions. Moreover, we explore how these design issues might be addressed by hypermedia modeling techniques, given the similarities between these two kinds of interactive systems and the maturity reached in hypermedia development.

Introduction

When facing the development of virtual environments (VEs), most developers turn to toolkits or authoring tools like those reported in Kessler, Bowman, and Hodges (2000) in which they pick different components out of a repository and build their environment from scratch in an unsystematic fashion driven by technology rather than by requirements. In such a scenario, abstraction is absolutely despised. Instead of describing the VE using concepts and relationships that describe the problem to be solved in terms of the universe of discourse (such as rooms, collections, or paintings in a virtual museum) as it is done in conceptual models (Hofstede & van der Weide, 1993), it is expressed using technical terms and implementation units, such as cylinders, spheres, or textures. But such a technology-driven development strategy brings a number of disadvantages. Firstly, development is boiled down to 3D modeling and programming, so that the stakeholders can only take part in the evaluation, whether formative or summative, of prototypes. Involving stakeholders in all the phases of the development process, including design, is a basic requirement for any kind of interactive systems, as they know which objects, facts, concepts, and relationships are relevant in the domain of the application (Preece, Rogers, & Sharp, 2002). Secondly, the lack of a conceptual design process leads to little flexibility for changes with a high cost in resources when the environment does not meet the user requirements or when technological evolution suggests the addition of new services. And finally, this implementation-driven approach makes maintenance, interoperability, and software reuse difficult or nearly unfeasible. A conceptual model, which is independent from the implementation units, provides a picture of the system that can be understood by different people and that can
